

1. Introduction
The present study was part of a larger project to develop a self-report measure of the construct of 'self-esteem'.

2. Method
2.1. Subjects
The sample consisted of 1000 subjects, 500 males and 500 females, aged between 18 and 65 years.

2.2. Procedure
Subjects completed the inventory in a laboratory setting. The inventory was administered in a self-paced manner.

2.3. Instruments
The inventory was a self-report measure consisting of 100 items. Each item was rated on a 5-point scale from 1 (strongly disagree) to 5 (strongly agree).

2.4. Data analysis
The data were analysed using a Rasch scaling procedure. This procedure allows for the estimation of the location and spread of the construct being measured.

2.5. Results
The results of the Rasch scaling procedure are presented in Table 1. The table shows the estimated location and spread for each item.

2.6. Discussion
The results of the Rasch scaling procedure provide a clear picture of the distribution of the construct being measured.

2.7. Conclusions
The Rasch scaling procedure is a powerful tool for the analysis of self-report data. It allows for the estimation of the location and spread of the construct being measured.
